1. Initial Placement

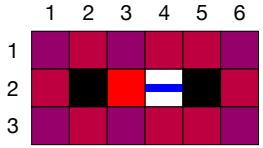

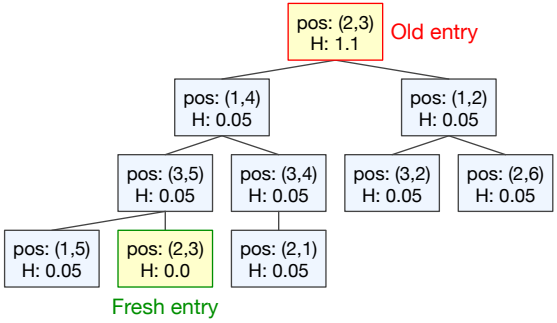

All class cells are placed. Cells (2,4) and (2,3) have the highest entropy, as paths must exit there.

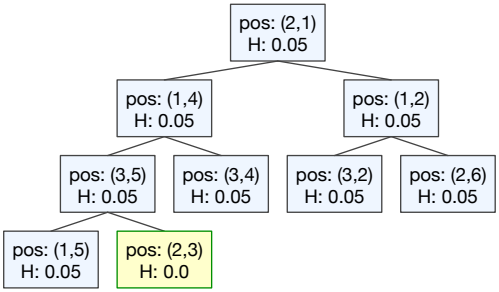

2. Observe and Propagate

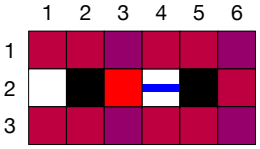

Cell (2,4) is collapsed, propagation updates (2,3) reducing its entropy to zero. A fresh entry for (2,3) is inserted while the old entry will be removed at the next observation.

3. Remove old entry

4. Next Cell Collapse

The root (2,1) is removed from the heap and collapsed into an empty tile. The process is repeated.
